

Q. 56

Function merge(intervals):

if interval is empty:

return []

Step 1: sort intervals by their start values sort intervals based on intervals[0] ascending.

Step 2: Initialize merged list with the first interval
merged = [intervals[0]]

Step 3: Iterate through the rest of the intervals
for i from 1 to length(intervals)-1:

current = intervals[i]

last merged = merged[last_index]

check for overlap: current.start <= last merged end
if current[0] <= last merged[1]

Merge by extending the end time

last merged[1] = max(last merged[1], current[1])

else

No overlap: add as a new interval

merged.append(current)

return merged
